Description

The present invenţi n relates to a method of increasing the viscosity of a chocolate composition containing cocoa butter so that said composition will be substantially more flowable at a temperature well above the normal melting point of the cocoa butter.

Fats and oils are widely used in food, cosmetic and pharmaceutical products. Unfortunately, many naturally occurring oils and some fats have very low melting (flow) points and, therefore, impart an undesired physical characteristic to products which contain them. The separation of peanut oil in peanut butter is one typical example of the problem. Another example is the tendency of natural chocolate products containing cocoa butter to stick to product wrappers or to fingers, particularly during the summer months. The separation of butter from dough in the preparation of dough for pastry products, such as croissants or danish pastry, and the surface greasiness of such products is yet another example of an adverse product characteristic resulting from the low melting and flow point of a fat-containing product.

Oils and fats can be immobilized by hydrogenation but this approach is expensive and leads to physiological properties which may be undesirable in food products. Hard fats may be substituted for oils or lower melting point fats, but this substitution often changes the texture or other eating characteristics of the product. Immobilization of fats may also be achieved by the use of stabilizers. However, such additives are often expensive and may be comprised of undesirable synthetic materials. Moreover, there is a consumer trend away from food products which contain unnatural additives. In addition, in the case of some products, such as chocolate, the addition of a stabilizer may constitute a material departure from the standard of identify for "chocolate", whereby depriving a manufacturer of the ability to call a particular product a "chocolate" product.

Canadian Patent No. 979,730 discloses one attempt in the prior art to overcome the undesirable effect of a low melting point in a fat or oil containing system by the incorporation of colloidal silicone dioxide having a defined particle size. As described in the aforesaid patent, the oil is heated and intimately mixed with the silicone dioxide particles using high shear mixing. Thereafter, a polyol bridging compound is added in order to bind the oil in a stable matrix formed by the silicone dioxide particles and the polyol. The resulting product is a shortening which has a thick-spreading consistency and exhibits little change in viscosity at elevated temperatures. The undesirability of adding silicone dioxide particles t food products is believed to be self-evident.

Attempts have been made t produce a heat-resistant chocolate by incorporating crystalline hydrophillic substances such as dextrose, maltose, mannitol or sorbitol as humectants and exposing the chocolate, after casting, to a moist atmosphere for an extended period of time. See, for example, U.S. Patent No. 4,446,166. The pr - ducts of that process have an undesirable surface appearance as a result of sugar bloom, and the flowability of the fat immediately below the surface of the chocolate is not altered by the treatment.

Various types of polyols such as glycerine, sorbitol, mannitol and propylene glycol have been employed in liquid, semi-solid or solid food applications as bodying agents, humectants, antioxidants, preservatives, solubilizing agents and the like. For example, Japanese Patent Application 50-96979 discloses the preparation of fat and oil compositions containing high HLB emulsifiers and inter alia, polyols, as solubilizers. U.S. Patent 3,694,233 discloses gravy compositions with high water and oil content, which contains between 9 and 66% by weight of glycerol or a preservative. Polyols are also disclosed as preservatives to reduce spoilage in U.S. Patent No. 4,252,834. However, until now the prior art has not recognized that polyols have the ability to dramatically increase the viscosity of fats and oils.

It is an object of the present invention to provide a novel method for immobilizing the fat or oil in a chocolate composition containing such materials.

It has now been discovered that the addition of a liquid polyol to a chocolate composition containing cocoa butter results in a substantial increase in the viscosity of the fat. This increase in viscosity, once achieved, appears to be unaffected by increases in the temperature of the composition, even though the temperature reaches levels well above its normal melting point. The increase in viscosity caused by the present invention is such that the chocolate composition containing cocao butter appears to be substantially immobilized, and the resulting products exhibit the appearance and characteristics of a solid, even at temperatures which are well above the melting point of the chocolate composition containing cocoa butter. Thus, chocolate will appear to be unmelted and will not stick to wrappers or fingers, even though the chocolate is at a temperature well above the flow point of the cocoa butter contained in the chocolate. Th method of the present invention is characterized in comprising mixing 0.2 to 5 wt% of a liquid polyol such as a polyol selected from the group comprising glycerine, sorbitol, propylene glycol, mannitol, corn syrup and combinations and solutions thereof to a chocolate mixture after it has been tempered.

The exact mechanism by which the increase in viscosity and immobilization of the fat of the chocolate composition are achieved is not known. However, it is presently believed that the increased viscosity is due t some type of chemical interaction between the fat and th polyol. This beli f stems from the fact that, after the addition of the polyol, the viscosity of the fat-containing system appears to increase with

increasing tim and/or temperature and, up to a point, by increasing the amount of polyol added. Moreover, after cooling, the increased viscosity appears to be unaffected by increases in temperature which are substantially above both the temperature at which the polyol was initially added as well as the melting point of the fat. Further, in order to achieve the desired increase in viscosity, the polyol must either be a liquid or be in solution when mixed with the fat or oil. All of the foregoing characteristics are consistent with the possibility of a chemical reaction between the fat and the polyol.

When a polyol is added to such a marginally flowable system containing a substantial proportion of solids, the resulting increase in viscosity produces a system in which the chocolate mixture is substantially non-flowable and, for practical purposes, behaves like a solid even though the temperature of the system is raised to a level where the fat of the chocolate composition is actually a liquid, albeit a highly viscous liquid.

Polyols which may be used in the invention are straight or branched chained hydrocarbon compounds containing at least two hydroxyl groups on the carbon skeleton. Compounds which include other functional groups, e.g., double bonds or carboxyl groups, may also be employed, provided that at least two hydroxyl groups are also present. There is no upper limit to the number of carbon atoms or hydroxyl groups which may be present on the structure. Polyols are not generally soluble in fats or oils and it is a critical feature of the invention that the polyol be in a liquid form when it is mixed with the fat. Accordingly, polyols which are naturally occurring liquids, such as glycerine, are preferred as a matter of convenience, although other polyol materials which readily form solutions having a substantial concentration of the polyol are acceptable. For example, sorbitol is commercially available as a 70% solution in water. Other materials which can be utilized in the invention include propylene glycol, mannitol, corn syrup (e.g., 42 D.E.), or a hydrogenated corn syrup, such as the mixture commercially available under the trademark Lycasin which comprises sorbitol and a variety of hydrogenated polysaccharide compounds.

Ordinarily, the amount of polyol added to the system will be between 0.2 and 5 wt. %, preferably 0.5 and 2 wt. %. At low polyol levels, an increase in the amount of polyol results in some increase in the viscosity of a fat-containing system, but this effect does not continue at higher polyol levels. Moreover, there appears to be a direct relationship between the amount of fat present in a system and the amount of polyol which will be useful in producing an increased viscosity.

No special mixing conditions ar required to form the novel products of the invention. However, it is apparent that the p lyol must be in liquid form and be homogeneously dispersed in the chocolate composition containing system. To this end, the chocolate containing system must be in a somewhat flowable form when th polyol is added. Increased flowability may be achieved by mixing the fat-containing material with the polyol at a slightly elevated temperature, e.g. 24°C—49°C (75—120°F). It has also been observed that the time required to achieve the increased viscosity directly varies with the temperature of the mixture. Irrespective of the temperature, however, it may be desirable to hold the mixture of the polyol and chocolate composition-containing material in storage for periods of time ranging from about 5 minutes to 60 minutes or more in order to reach a desired viscosity level before further using or processing the material. The length of time the product is held will, of course, depend on the specific nature of the product and the further proceeding steps. In those instances where a greatly increased viscosity would hinder the formation of the first product, the products may be rapidly formed after addition of the polyol and, thereafter, be held at conditions which would favor a further increase in viscosity.

A particularly preferred application of the invention is the formation of chocolate products which will remain relatively hard at elevated temperatures where the cocoa butter content of chocolate normally flows. At the average temperature of human skin 33°C (91 degrees F), the fat content of chocolate is soft and flowable, which serves to explain why a piece of chocolate normally sticks to a person's fingers if it is held for any significant length of time. Chocolate also sticks to wrappers at summer temperatures. If the fat content of the chocolate is immobilized by the addition of a polyol, it will not flow even at temperatures well above 33°C (91°F).

In a typical process for manufacturing chocolate or chocolate coated products in accordance with the invention, any conventional chocolate formulation may be employed. Such formulations normally contain chocolate liquor, whole milk solids, sugar and, most importantly, cocoa butter. However, any other ingredients, all of which are well known in the art, may also be used. Typically, the foregoing ingredients are mixed, refined, conched and standardized as to viscosity and are thereafter tempered by heating to an elevated temperature, e.g., 49°C (120°F), cooled to a lower temperature, e.g., 26°C (79°F) and reheated to a molding or enrobing temperature of about 29.5°C (85°F). The chocolate is then utilized to form a molded finished product or to enrobe or coat a pre-formed center. In either event, the chocolate is eventually cooled or refrigerated after it is put into the final product form.

In accordance with the present invention, 0.2 to 5 wt. % of a liquid polyol, e.g., glycerine, is added to the flowable chocolate mixture after it is tempered and before it is molded or used as an enr bing material. The liquid polyol is mixed with the chocolate at a t mperatur in the range of 24°C to 35°C (75 to 95°F), preferably, 29°C to 33°C (84 to 91°F) and held at that temperature for a peri d of 1 to 60 minutes, e.g., 8 minutes. Alterna-

tively, the chocolate may be immediately used after addition of the polyol, provided that it is held at the molding or enrobing temperature for a time sufficient to permit the fat and polyol to interact and produce an increase in viscosity before it is refrigerated for demolding. The length of the holding time is a matter of choice based upon the fat content of the particular formulation being employed, the amount of polyol, the temperature, and the fluidity or viscosity requirements needed for efficient processing of the chocolate to form the desired end products. However, because the increase in viscosity which results from the practice of the invention is heat irreversible, it is important that careful attention be paid to the holding time and temperature so as to ensure that the desired increase in viscosity is obtained without interfering with the ability to process the chocolate into finished products.

The invention will be further understood from the following illustrative examples:

Example 1

The results obtained with semisweet chocolate and 1% polyol are shown in Table 1 below (maximum scale reading is 100).

TABLE 1

Speed	Control (Spindle 3)	With 1% Glycerine (Spindle 5)
1	26.8	off scale
2	38.5	off scale
5	41.0	off scale
10	54.0	off scale

Example 2

A chocolate was prepared to the following formula:

Ingredient	Parts by Weight
Chocolate liquor	10.50
Whole milk solids	22.95
Sugar	45.0
Cocoa butter	21.00
Vanillin	0.05
Glycerine	1.00

The above material was mixed in a 5 qt. Hobart mixer for 5 minutes. The mixed material was refined by running it through a 3 roll laboratory refiner (a horizontal 3 roll mill) where the particule size was reduced to approximately 22 µm. Thereafter the chocolate was conched by mixing in a 5 quart Hobart mixer for 5 hours with a heat gun blowing on the mix. The conching temperature was 57°C (135°F). The chocolate prepared as described above was tempered by heating to 49°C (120°F), cooling to 26°C (79°F), and reheating to 29.2°C (84.5°F).

One part of glycerine was added to tempered chocolate prepared in the foregoing manner and stirred vigorously while being held at 29.2°C (84.5°F) for a period of ten minutes. Thereafter, the chocolat was poured into one ounce molds which were being vibrated during the molding process. The chocolate in the molds was refrigerated for thirty minutes and then demolded.

When chocolate pieces prepared in the foregoing manner are heated with a heat gun at 49°C (120°F), the pieces soften slightly but do not become fluid. In contrast, chocolate pieces prepared from the same formulation without glycerine are more or less fluid and flow at the elevated temperature.

In a separate experiment, a chocolate formulation is prepared using the method and formulation described above, except that 10 parts of dextrose are substituted for 10 parts of sucrose, no glycerine is added, and the molded bars are stored for 21 days at 29.4°C (85°F) and 85% relative humidity, as described in US—A—2,904,438. When chocolate bars prepared in that fashion are heated to 49°C (120°F), the presence of a heat resistant skin on the surface of the chocolate is noted, but the chocolate beneath the skin is flowable.

Example 3

Imitation chocolate may also be formed in accordance with the invention. In such products, the amount of cocoa butter is greatly reduced and hard butter is substituted. A typical formulation is as follows:

Ingredient	Parts by Weight
Cocoa	5.40
Non-fat dry milk	16.50
Sugar	45.00
Hard butter	32.05
Vanillin	0.05

The foregoing ingredients are mixed and refined, as previously described, and heated to 120°F. One part of glycerine is then added. The imitation chocolate is cooled to 85°F and is used as an enrobing agent for previously prepared centers. The chocolate coating does not stick to the fingers.

It will be readily apparent to those skilled in the art that a wide variety of food, cosmetic, pharmaceutical or other compositions can be formulated utilizing the method of the invention to produce a variety of novel products which may benefit from the ability to immobilize a low melting point fat or oil.

Claims

1. A method of increasing the viscosity of a chocolate composition containing cocoa butter s that said composition will be substantially n n-flowable at a temperature well abov the normal melting p int of the cocoa butter characterized in comprising mixing 0.2 to 5 wt. % of a liquid polyol such as a polyol selected from the group comprising glycerine, sorbitol, propylene glycol, mannitol, corn syrup and combinations and solutions

thereof to a chocolat mixture after it has been tempered.

2. The method of claim 1 wherein said liquid polyol is added in an amount of 0.5 to 2 % by weight.

3. The method of claim 1 wherein said liquid polyol is a solution containing said polyol.

4. The method of claim 1 wherein said liquid polyol is glycerine.

5. The method of claim 1 wherein said composition contains at least 20 wt. % of solid particles.

6. The method of claim 1 further including the steps of maintaining the chocolate composition including the polyol at a temperature above 24°C (75°F) at which said composition is flowable for a time between 1 and 60 minutes to permit said cocoa butter and polyol to interact and produce an increase in viscosity and thereafter cooling said composition to form a solid chocolate composition product.

7. The method of claim 6 wherein said time is 8 minutes.

8. The method of claim 6 wherein said temperature is between approximately 24° to 35°C (75° to 95°F).

9. The method of claim 8 wherein said temperature is between approximately 29° to 35°C (84° to 91°F).

Patentansprüche

1. Verfahren zum Erhöhen der Viskosität einer Schokoladezusammensetzung, die Kakaobutter enthält, so daß die Zusammensetzung bei einer Temperatur, die deutlich über dem normalen Schmelzpunkt der Kakaobutter ist, im wesentlichen nichtfließfähig sein wird, gekennzeichnet durch Vermischen von 0,2 bis 5 Gew. % eines flüssigen Polyols, z.B. eines Polyols, das aus der Gruppe ausgewählt wird, die Glycerin, Sorbitol, Propylenglycol, Mannitol, Stärke-sirup und Kombinationen und Lösungen derselben umfaßt, mit einer Schokolademischung, nachdem diese richtig abgestimmt worden ist.

2. Verfahren nach Anspruch 1, wobei das flüssige Polyol in einer Menge von 0,5 bis 2 Gew. % zugesetzt wird.

3. Verfahren nach Anspruch 1, wobei das flüssige Polyol eine Lösung ist, die das Polyol enthält.

4. Verfahren nach Anspruch 1, wobei das flüssige Polyol Glycerin ist.

5. Verfahren nach Anspruch 1, wobei die Zusammensetzung wenigstens 20 Gew. % festige Partikel enthält.

6. Verfahren nach Anspruch 1, weiter beinhaltend die Schritte, de Schokoladezusammensetzung, die das Polyol enthält, auf einer Temperatur über 24°C (75°F), bei der die Zusammensetzung fließfähig ist, für eine Zeit zwischen 1 und 60 Minuten zu halten, um der Kakaobutter und dem Polyol zu gestatten, in Wechselwirkung zu treten und eine Erhöhung der Viskosität zu erzeugen, und anschließend die Zusammensetzung abzukühlen, um ein festes Schokoladezusammensetzungsprodukt zu bilden.

7. Verfahren nach Anspruch 6, wobei die Zeit 8 Minuten beträgt.

8. Verfahren nach Anspruch 6, wobei die Temperatur zwischen etwa 24° und 35°C (75°—95°F) liegt.

9. Verfahren nach Anspruch 8, wobei die Temperatur zwischen etwa 29° und 35°C (84°—91°F) liegt.

Revendications

1. Procédé en vue d'augmenter la viscosité d'une composition de chocolat contenant du beurre de cacao, de telle sorte que la composition soit pratiquement inapte à l'écoulement à une température bien supérieure au point normal de fusion du beurre de cacao, ce procédé étant caractérisé en ce qu'il consiste à mélanger 0,2 à 5% en poids d'un polyol liquide tel qu'un polyol choisi parmi le groupe comprenant la glycérine, le sorbitol, le propylène-glycol, le mannitol, le sirop de maïs ainsi que des combinaisons et des solutions de ceux-ci, à un mélange de chocolat, après l'avoir soumis à un équilibre de température.

2. Procédé selon la revendication 1, dans lequel on ajoute le polyol liquide en une quantité de 0,5 à 2% en poids.

3. Procédé selon la revendication 1, dans lequel le polyol liquide est une solution contenant ce polyol.

4. Procédé selon la revendication 1, dans lequel le polyol liquide est de la glycérine.

5. Procédé selon la revendication 1, dans lequel la composition contient au moins 20% en poids de particules solides.

6. Procédé selon la revendication 1, ce procédé comprenant en outre les étapes consistant à maintenir la composition de chocolat contenant le polyol, à une température supérieure à 24°C (75°F), température à laquelle la composition est apte à l'écoulement, pendant une période allant de 1 à 60 minutes, en vue de permettre au beurre de cacao et au polyol d'interagir et en vue d'obtenir une augmentation de la viscosité, tandis que l'on refroidit ensuite cette composition, pour obtenir un produit solide à composition de chocolat.

7. Procédé selon la revendication 6, dans lequel le temps est de 8 minutes.

8. Procédé selon la revendication 6, dans lequel la température est comprise entre approximativement 24° et 35°C (75° et 95°F).

9. Procédé selon la revendication 8, dans lequel la température est comprise entre approximativement 29° et 35°C (84° et 91°F).
